Relationship between bit error rate and bit rate

Overview

The bit error rate (BER), or perhaps more appropriately the bit error ratio, is the number of bits received in error divided by the total number of bits transferred. The bit. A bit error occurs when a single binary digit is flipped during transmission, meaning a logical '0' is mistakenly interpreted as a '1' by the receiver, or a '1' is read as a '0'. These errors arise because the physical signal representing the bit is distorted or contaminated as it travels through. In the fast-paced world of digital communication—where billions of bits travel through wires, fibres and wireless links every second—the concept of bit error rate (BER) is both fundamental and profound. It's the quiet measure of how many bits that were intended to arrive at a receiver correctly. For finding the BER vs SNR: y = hx + n* (10^ (- (SNRdB) / 20)) from this above equation I can find BER vs SNR. But I didn't get the relation between BER, distance and SNR. And BER of EVE is small at d=1. Signal-to-Noise Ratio (SNR) measures the strength of the desired signal relative to background noise, serving.
