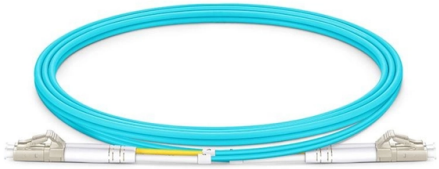
# Two-core optical module



## Overview

The Key Differences Between 1-core, 2-core, Single o In optical modules, "core" refers to the light-transmitting channel in the fiber. A 1-core module uses.

## Key Takeaways

A 2-core optical module uses two fiber cores to transmit data simultaneously, effectively doubling the transmission capacity compared to a 1-core module.

## Overview

A 2-core optical module is a type of optical transceiver used in fiber optic communication systems. In this context, "core" refers to the light-transmitting channel within the fiber. A 2-core module contains two separate cores, allowing data to be sent and received simultaneously over two channels, which increases bandwidth and improves efficiency compared to a single-core module.

This is analogous to a two-lane highway where two streams of traffic can flow at the same time.

## Structure and Function

Optical modules, including 2-core types, typically consist of: TOSA (Transmitter Optical Sub-Assembly): Converts electrical signals into optical signals using a laser diode or LED.

### ROS

A (Receiver Optical Sub-Assembly): Converts incoming optical signals back into electrical signals using a photodetector. Functional circuits and interfaces: Manage signal processing and ensure compatibility with the host device. The 2-core design allows dual-channel transmission, which can be particularly useful in high-speed networks such as 10GbE SFP+ or higher, supporting data center and enterprise applications.

Fiber Type Considerations2-core modules can be implemented with either single-mode (SM) or multi-mode (MM) fibers: Single-mode (SM): Smaller core, light travels in a single path, ideal for long-distance transmission with minimal signal loss. Common wavelengths include 1310nm and 1550nm. Multi-mode (MM): Larger core, supports multiple light paths, suitable for short-distance applications, typically using 850nm wavelength.

Applications2-core optical modules are widely used in: Data centers for high-speed interconnects. Enterprise networks to increase port capacity without additional fiber runs. Telecommunications for long-haul or metro networks when combined with single-mode fibers.

### Advantages

Higher throughput: Dual cores allow simultaneous bidirectional data transfer. Flexibility: Compatible with SFP, SFP+, and other modular transceivers. Scalability: Supports network expansion without major infrastructure changes.

In summary, a 2-core optical module enhances data transmission efficiency by using two fiber channels, making it suitable for high-speed, high-capacity networking environments while supporting both single-mode and multi-mode fiber applications.
